COMPLETE SPECIFICATION

SHEET METAL ARTICLE

WE, GOSPEL RESOURCE LIMITED, incorporated in the State of Victoria, Commonwealth of Australia of 8 Horne Street, Thomastown, Victoria 3074, Australia, hereby declare the invention, for which we pray that a patent may be granted to us, and the method by which it is to be performed, to be particularly described in and by the following statement:-

SHEET METAL ARTICLE

This invention relates to the manufacture of sheet metal articles.

It frequently happens when two sheet metal components are required in a composite structure that it is convenient to combine the two components into a single article so that both may be made simultaneously by a single stamping and/or pressing operation. Thus the respective components become functional zones of a single article spaced apart as needed in the composite structure by an intermediate, inherently functionless zone. Hitherto, for simplicity of manufacture of such articles, it has been commonplace to utilise a workpiece big enough to extend from one functional zone to the other, and to tolerate the wastage of material implicit in having in the finished article a sheet or strip of the metal integral with the functional zones and extending from one to the other.

A typical article of the kind in question is a fixing clip used for the concealed affixture of sheet metal roofing sheets. One well-known roofing sheet manufactured and sold under the trade mark "KLIP-LOK" comprises a sheet of coated steel having three substantially channel-sectioned ribs extending for the length of the sheet. There is one rib at each edge and an intermediate rib substantially coinciding with the centre line of the sheet.

Those roofing sheets are secured to purlins or the like by strip-shaped clips, which have, at each end, formations adapted to snap-engage, or be snap-engaged by, the ribs of the roofing sheet. The arrangement is such that a

N.Z. PATENT OFFICE

1 JUL 1992

clip may be applied with one end formation fitting over an edge rib of a previously laid sheet and extending to a point where its other end formation may engage within the central rib of the next-applied sheet. The clip may be secured to the supporting timbers for the roof deck by nails or the like through affixture holes near each end of the clip, and the next sheet applied so that an edge and the central rib snap over the respective end formations of the clip. Thus, once the clip has been applied to the purlin, the material intermediate the end formations ceases to serve any functional purpose; its initial presence being purely to assist in the manufacture of the clip, to ensure that the functional ends thereof are correctly spaced apart, and to facilitate the handling of the clip and its installation by the person laying the roof.

The present invention was devised primarily for the manufacture of such clips. It is described primarily in relation thereto hereinafter, but it will be appreciated that it is generally applicable to many sheet metal articles in which a relatively functionally unimportant zone is provided for the purpose of spacing functional zones and to enable the article to be made and handled as a single piece.

An object of the present invention is to save materials in the manufacture of such articles by reducing the size of that part of the workpiece corresponding to the intermediate zone of the finished article.

With the above and other objects in mind, the present invention provides a method of making a sheet metal

NEW ZEALAND
PATENT OFFICE

RECEIVED

article comprising the steps of forming a workpiece of lesser area than that of said article, slitting an area of said workpiece corresponding to a non-functional zone of said article to render said non-functional zone extendable, shaping the remainder of said workpiece as needed, and extending said non-functional zone to produce said article.

In its preferred aspect the invention consists in a method of making a sheet metal article comprising two shaped functional zones spaced apart by an intermediate zone, comprising the steps of shaping each functional zone on a workpiece having an intermediate zone shorter than that required in the finished article, slitting the said shorter intermediate zone to render it extendable, and extending said slitted shorter intermediate zone to provide the full length article.

The invention extends to articles when made by the method of the invention.

The steps of slitting and subsequently extending the non-functional zone may be performed in a number of ways utilising various slitting patterns and corresponding modes of extension. Furthermore, the extension of the zone may be effected either before or after the remainder of the workpiece has been shaped to conform to the required article.

According to a first class of embodiments of the invention the slitting is such as to define a plurality of interconnected tongues extending in the longitudinal direction of the non-functional zone, that is to say the direction in which it is to be extended, and the extension of the non-

NEW ZEALAND
PATENT OFFICE

CEIVED

functional zone in that direction is effected by folding or unfolding the tongues about their respective root lines.

According to a second class of embodiments of the invention, the slitting is such as to define a plurality of interconnected strips extending in the transverse direction and the extension is effected by stretching the work piece so as to at least partly reorient the strips into the longitudinal direction by deformation of the metal at the junctions of the strips.

By way of example, several embodiments of the above-described invention are described in more detail hereinafter with reference to the accompanying drawings, in which:

Figures 1 and 2 are diagrammatic plan view of a roof sheet fixing clip according to the invention at partly and fully finished stages of its production respectively;

Figures 3 and 4 are views similar to Figures 1 and 2 of roof sheet fixing clips according to a second embodiment of the invention;

Figures 5 and 6 are views similar to Figures 1 and 2 of roof sheet fixing clips according to a third embodiment of the invention;

Figures 7, 8 and 9 show fourth, fifth and sixth embodiments respectively;

Figures 10 and 11 show a seventh embodiment of the invention.

In the drawings, the functionally shaped end zones A and B of the clips, which form no part of the present invention, are merely shown in part. In each instance the

- 6 -

area between them constitutes an intermediate non-functional zone as that term is used herein.

It will be seen from Figure 1 that the intermediate zone of the embodiment illustrated thereby has one U-shaped and two L-shaped slits 5, 6 and 7 cut in it. Those slits may be made simultaneously with the press-forming of the respective end zones A and B. It will be seen that the U-shaped slit 5 defines a first tongue 8 extending from a root line at 9 to a free tip 10.

The tongue 8 has formed in it a second narrower tongue 11 extending from a root line indicated at 12 to a free tip 13. The tip 13 of the tongue 11 is integral with the functional zone B of the clip.

Figure 2 shows the clip in its finished or extended form, wherein tongue 8 has been folded in a clockwise direction about its root line 9 and tongue 11 has been folded in an anti-clockwise direction about its root line 12, so that tongue 8 projects from the original intermediate zone and the narrower tongue 11 projects correspondingly from tongue 8.

The clip of Figures 3 and 4 is a modification of that of Figures 1 and 2 in that the slit pattern applied to the whole of the intermediate zone of Figure 1 is duplicated and applied to each half of a doubly long intermediate zone of Figure 3. The patterns in each half zone are mirror images of each other and the narrower tongue of one half is integral with that of the other half instead of with a functional zone as in Figure 2. The tongues of each half of the intermediate zone in Figures 3 and 4 have been given the same reference

NEW ZEALAND
PATENT OFFICE

numerals as their counterparts in Figure 1, but with a and b suffixes, and it is thought that no further description is required.

The clip of Figures 5 and 6 is a further
5 modification of that of Figures 1 and 2 in that the slit pattern applied to the intermediate zone of the former has been re-applied, with appropriate narrowing, to the narrower
10 tongue to permit a second stage of extension. The reference numerals of Figures 5 and 6 again correspond to those of
15 Figures 1 and 2 with appropriate suffixes and it is thought that the drawings will be self explanatory to the skilled reader. It will be apparent also that in other similar embodiments this mode of slitting could be further replicated to produce three or more stages of extension of a single zone of the workpiece.

The clips illustrated and described above all belong to the said first class of embodiments whereas those described below all belong to the said second class of embodiments.

The clip illustrated by Figure 7 may be the same
20 functionally as that of Figures 1 and 2. It includes functional zones A and B separated by an intermediate zone. The Intermediate zone is slit during manufacture as indicated in Figure 7, by an array of closely spaced parallel lines of slits. The individual slits 15 in each line are staggered and
25 overlap. For preference every second line terminates with half-length end slits 16 extending inwardly from the edges of the original workpiece. After the workpiece has been slit as shown in Figure 7, its functional zones A and B may be grasped

and pulled apart a pre-determined extent to expand the intermediate zone wherein the material between the individual slits is bent and/or stretched to form an expanded grid of material extending from one functional zone to the other.

5 The clip illustrated by Figure 8 is a modification of that of Figure 7 in that the intermediate zone is split longitudinally by slit 17 and each half is slit transversely by a plurality of slits 18 similar to the end slits 16 of Figure 7. This allows the transverse slit pattern to be less
10 complex than in the earlier embodiment. When pulled apart to expand the intermediate zone, the strips defined by the transverse slits 18 have been reoriented by 90°. This may be difficult to achieve in practice and a lesser degree of stretching may be used if preferred.

15 The clip of Figure 9 shows a further simplification of slit pattern. It is thought that in the light of the description generally, these figures will now be self explanatory and this embodiment needs no further description.

 The finished clips illustrated by Figures 7, 8 and 9
20 are somewhat idealised. In practice it may be preferred to follow the stretching step by a flattening of the expanded intermediate zone, for example, by pressing or rolling or the like, especially where a high degree of reorientation of the individual strips is resorted to.

25 The clip of Figures 10 and 11 uses slits 19 of approximately triangular configuration, together with a triangular cut-out 20, and arcuate slits 21. When pulled apart to expand the intermediate zone, the strips defined by

the slits 19, cut-out 20 and slits 21 will have been reoriented, as is clearly shown in Figure 11. As for the clips of Figures 7, 8 and 9 it may be preferred to follow the stretching step by flattening the expanded intermediate zone.

5 The illustrated embodiments of the invention described above all have two functional zones spaced apart by an intermediate non-functional zone extending from one functional zone to the other. It is emphasised however that the invention is not so limited. It may be that an article has three or more functional zones and a corresponding plurality of non-functional intermediate zones. In such instances each intermediate zone may be independently extended, not necessarily in a common direction.

15 Furthermore, it may be that a functional zone has no direct relationship with another identifiable zone, it may simply require positioning with respect to the remainder of the article generally. In such instances a reduced area, appropriate misshapen workpiece may be made and subsequently a part thereof may be slit and extended in accordance with the invention to modify its shape and expand its area to suit the finished article.

20

WHAT WE CLAIM IS:

1. A method of making an expanded sheet metal workpiece comprising the steps of:
 - (a) slitting an area of a non-functional zone of said workpiece, thereby forming slits to render said non-functional zone extendable, said slits defining a plurality of interconnected tongues, each of said tongues extending in a longitudinal direction of said non-functional zone and in a direction at an angle to said longitudinal direction, each of said tongues having a root line, a major portion of said slits extending linearly with some of said slits extending in the longitudinal direction and some of said slits extending at an angle to said longitudinal direction, at least some of the longitudinally and angularly extending slits being interconnected with each other;
 - (b) subsequently extending said non-functional zone in said longitudinal direction by expansion of the non-functional zone by at least 100%, said expansion causing folding of said tongues about said root line, thereby producing said expanded sheet metal workpiece.
2. A method as claimed in claim 1, wherein said expanded sheet metal workpiece includes two functional zones, one at each end of said non-functional zone.

3. A method as claimed in claim 1, wherein said non-functional zone prior to said slitting of said area and said extending, is shorter than the non-functional zone subsequent to said slitting and said extending.
4. A method as claimed in claim 1, further comprising flattening said non-functional zone subsequent to said slitting and said extending.
5. A method as claimed in claim 1, wherein said angle is approximately 45°.
6. The method as claimed in claim 5, wherein said expansion causes twisting and folding of said tongues about said root line, thereby producing said expanded metal workpiece.
7. A method as claimed in claim 1, wherein said angle is approximately 90°.
8. The method as claimed in claim 1, wherein said expansion causes twisting and folding of said tongues about said root line, thereby producing said expanded metal workpiece.
9. A method of making a sheet metal article substantially as hereinbefore described with reference to the accompanying illustrative drawings.
10. A sheet metal article when produced by the method of any one of Claims 1 to 9 inclusive.
11. A sheet metal article substantially as hereinbefore described with reference to the accompanying illustrative drawings.
